Vol. LXVIII. Supplementary Number. No. 9

On the Parallax and Proper Motion of the Double Star Krueger 60 (Burnham, Gen. Cat., if76r). By E. E. Barnard. (Plate 14.)

The History of Krueger 60.
Professor Krueger, in his catalogue of the Astronomische Gesellschaft, covering the zone $+55^{\circ}$ to $+65^{\circ}$, noted with the meridian instrument many stars which were double. He made a rough estimate of the quadrant and distances of these stars and of their magnitudes.

In 1890 Professor Burnham measured 67 stars from Krueger's list with the 12 -inch and 36 -inch telescopes of the Lick Observatory (Pub. L.O., vol. ii.). The star No. 60 was among those measured. Krueger's note on this object is :
"Dupl. 12 " pr. com. $9{ }^{\circ} 3$."
In measuring the principal star, Professor Burnham found that it was a wide and unequal double.

Of these A C is the Krueger pair.
No other measures were made of these stars until 1898, when Dr. Eric Doolittle remeasured them with the 18 -inch Brashear telescope of the Flower Observatory (A.J., vol. xxi. p. 47).

Doolittle's measures showed that the pair AB had a strong proper motion ( $0^{\prime \prime} \cdot 93$ in the direction $247^{\circ} 9$ ). His measures are-

$$
\left.\begin{array}{rrrrr}
\mathrm{I} 898.446 & \mathrm{I} 40^{\circ} \cdot 66 & 3^{\prime \prime} \mathrm{I} 9 & 9^{\circ} \mathrm{I}-\mathrm{m}-\mathrm{m} \cdot 5 & \mathrm{AB} \\
& 5^{8 \cdot 7 \mathrm{I}} & 34.39 & 9 \cdot 4 & \mathrm{AC}
\end{array}\right\} 5 \mathrm{n} .
$$

Subsequent measures fully confirmed these results.
In $A . J .$, vol. xxi. p. 64, I have given measures of these stars which are in accord with the motion derived by Doolittle. (In the

Krueger 60. 1903•5.

Fig. I.
measures of $A B$ in that paper there is a misprint of $2^{\prime \prime} \cdot 23$ for $3^{\prime \prime} \cdot 23$.) In A.J., vol. xxiii.* pp. 169-172, I have given more observations, with a diagram showing the probable orbital motion of AB. A few years' measures soon showed that this was really a physical pair in rather rapid orbital motion. I also called attention to the probable proximity of these stars to our solar system. Acting on this last idea, I began in 1900 a series of measures, with the 40 -inch telescope, of $A$ and $C$ for the parallax of $A$.

* On p. 171 in that paper, the motion in right ascension should be - $\mathrm{o}^{8 \cdot 107}$ instead of $-\mathrm{I}^{8} 606$, and on p. 172 the seconds in the right ascension should be $3^{22^{8}} 00$ instead of $32^{8 .} 69$. In that paper I derived the proper motion $\mathrm{o}^{\prime \prime} \cdot 95 \mathrm{I}$ in the direction $24^{\circ}{ }^{\circ} 3^{\circ}$.

In the Astrophysical Journal, vol. xx. p. 128, for Sept. 1904, Dr. Schlesinger published his results of the parallax of A derived from photographs made with the 40 -inch telescope. Dr. Schlesinger found a parallax of about $\frac{1^{\prime \prime}}{4}$, verifying the prediction of its nearness to us. I will give, later on, his final values for the parallax.

Additional measures are given by Professor Burnham in Publications of the Yerkes Observatory, vol. ii., 1903, p. 67.

This is briefly the history of this remarkable stellar system.
In May of 1903 I measured the position of $A$ with respect to Helsingfors-Gotha A.G.C. 13177. From the measures the place of A is

$$
\begin{aligned}
& 1903 \cdot \circ a=22^{\mathrm{h}} 24^{\mathrm{m}} 32^{8 \cdot} \cdot 09 \\
& \delta=+57^{\circ} \mathrm{I} 2^{\prime} 38^{\prime \prime \prime} \cdot 5 \\
& \text { Proper motion }-0^{\mathrm{g} \cdot \mathrm{IO}} \mathrm{IO}-0^{\prime \prime} \cdot 3^{82} .
\end{aligned}
$$

The star is Helsingfors-Gotha A.G.C. I3170.

## Determination of the Parallax of A .

The present paper gives an investigation of the parallax of the star A from the visual micrometer measures made with the 40 -inch telescope.

The micrometer screw and the tube of the 40 -inch are both of steel. I have found from about ten years' experimental measures in the Pleiades (which are soon to be published) that the focus of the 40 -inch glass shortens from summer to winter by an extreme change of $\frac{3}{4}$ inch. In the meantime the steel tube shortens $\frac{1}{2}$ inch. The temperature change in the micrometer screw will correct $\frac{1}{2}$ inch of the total change of the focus of the object-glass. There remains uncorrected, therefore, $\frac{1}{4}$ inch of the extreme focal change. The exact amount of this uncorrected change, from the measures of the Pleiades referred to above, is 0.0032 inch ( 0.08 Imm .) for each degree of temperature. This would cause an extreme error in the measures of Krueger 60 for temperature of not quite $0^{\prime \prime} \cdot 0 \mathrm{r}$, and in the main it would not be appreciable. I have, therefore, not thought it necessary to correct the observations for temperature changes. I have not felt sure that the correction would be real. The corrections for aberration, being insensible, have been omitted.

All of the calculations for the parallax of this star were made, under my supervision, by my niece, Miss Mary Ross Calvert, who, through the courtesy of Mr. Andrew Carnegie, is at present my assistant. They have been carefully checked throughout, and seem to be free from errors. The observations, corrected for refraction, were first freed from proper motion. The parallax factors were then computed by Bessel's formulæ, as given in Chauvenet, vol. i. p. 695, fifth edition, where the parallax factor is

$$
R m \cos (\odot-M)
$$

in which R and $\odot$ are the distance and longitude of the Sun ; $m$ and $M$ being derived from the formulæ
$m \cos \mathrm{M}=\sin \alpha \sin \mathrm{P}+\cos \alpha \sin \delta \cos \mathrm{P}$
$m \sin \mathrm{M}=(-\cos \alpha \sin \mathrm{P}+\sin \alpha \sin \delta \cos \mathrm{P}) \cos \omega-\cos \delta \cos \mathrm{P} \sin \omega^{*}$
where P is the position-angle of the stars, $\alpha$ and $\delta$ the right ascension and declination, and $\omega$ the obliquity of the ecliptic.

The formula

$$
n+a x+b y+c p=0
$$

was used for the equations of condition. In all, there were seventysix equations of condition. From these the normal equations were derived in the usual manner. The normal equations were solved by the ordinary methods of elimination. As a check, they were also solved by Chauvenet's "second method of computing the weights of unknown quantities" (Chauvenet, vol ii., art. 35, p. 516 ), from which the weights were also derived. From these last, the probable errors were computed by the formulæ.

Probable error of parallax

$$
=\frac{\mathrm{P}}{\sqrt{w p}}
$$

where $w p$ is the weight of the parallax and

$$
\mathrm{P}= \pm 0.6745 \sqrt{\frac{\Sigma v^{2}}{n-3}}
$$

$v$ being the residuals derived by substituting the known values of $x, y$, and $p$ in the equations of condition. Similarly for the probable errors of $x$ and $y$, using for them the same value of $P$.

This method of determining the probable errors was kindly communicated to me by Dr. Schlesinger.

The proper motion used in these calculations was derived by me from a comparison with Professor Burnham's measures of AC in 1890 and my measures in the last of 1905. This value was $0^{\prime \prime} \cdot 968$ in the direction $246^{\circ} \cdot 49$.

The corrections for motion, to the observed distances, were computed by the formulæ given on page 696, vol. i., of Chauvenet's Theoretical and Practical Astronomy.

In Table I. are given the observations and their reduction to rgor.o, the last column being the residuals from the mean of the corrected distances. Table II. contains the equations of condition.

17. $-0.025+x+3.795 y+0.373 p=0$
29. $-0.054+x+3.828 y+0.548 p=0$
31. $-0.199+x+3.833 y+0.578 p=0$

Nov. 12. $\quad-0.297+x+3.866 y+0.726 p=0$
26. $-0.290+x+3.905 y+0.862 p=0$

1905 Nov. 26. $-0.337+x+4.904 y+0.863 p=0$
28. $-0.25 \mathrm{I}+x+4.910 y+0.875 p=0$ $+0.01 \mathrm{I}+76 x+204.053 y-14.804 p=0$

Corresponding equations were deduced for $y$ and $p$, the resulting normal equations being

$$
\begin{aligned}
& +0.0110+76.000 x+204.0530 y-14.8040 p=0 \\
& +2.2742+204.053 x+642.2801 y-52.9454 p=0 \\
& -8.5866-14.804 x-52.9454 y+38.0005 p=0
\end{aligned}
$$

The solution of these gives the following values :-

$$
\begin{aligned}
& p=+0^{\prime \prime} .249 \pm 0^{\prime \prime} .0105 \\
& y=+0.01 \mathrm{I} \pm 0.0063 \\
& x=+0.020 \pm 0.0182
\end{aligned}
$$

The value of the parallax of the star $A$ is, therefore,

$$
\pi=+0^{\prime \prime} \cdot 249 \pm 0^{\prime \prime} \cdot 0105
$$

This gives a distance of over 830,000 times that of the Sun. Light, therefore, requires 13 I years to come from Krueger 60.

Dr. Schlesinger has kindly supplied me with his final value for the parallax of this star. He determined the parallax by photography (during his connection with the Yerkes Observatory) from both right ascension and declination. These were from 19 plates taken with the 40 -inch telescope from 1903 to 1906. Three separate images were impressed on each plate. His results are-

$$
\begin{aligned}
\text { From R.A. } \pi & =+0.0 \cdot 257 \pm 0^{\prime \prime} 007 \\
\quad, \quad \text { Decl. } \pi & =+0.23^{8} \pm 0.01 \mathrm{I}
\end{aligned}
$$

It will be seen that the mean of these,

$$
\pi=+0^{\prime \prime} \cdot 248
$$

is essentially identical with my value.
The results with the same instrument, by visual and photographic methods respectively, in the one case by position-angle and distance, and in the other by right ascension and declination, should inspire confidence in both methods.

## Irregularity in the Proper Motion of A.

At present the stars A and B are moving almost directly away from C. This latter star, therefore, is a good one from which to determine the motion.

If B has a considerable mass ratio to A , a large irregularity in the proper motion of either star must occur because of the large apparent distance between the two. If their masses should be nearly equal, this deviation from uniformity of motion in either - star may amount to as much as $\mathrm{I}^{\prime \prime} \cdot 5$. This last mass ratio is not
improbable, in view of the investigations of Mr. Lewis of the Greenwich Observatory who found * that in some cases the apparently smaller star of a binary is really the more massive of the two. It is important, therefore, frequently to measure the position of $A$ with reference to $C$ and other stars in the field. By this means, in the course of time, its mass will become accurately known. For this reason I have kept the star on my observing list, and have made frequent measures of it and the stars mentioned. Of my own work there are now some seven or eight years' observations. Of course, for various reasons, where it is possible, it is best to use the measures of one individual.

The known history of these stars perhaps covers too short an interval for the observations to show any very decided irregularity in the motion of $A$. To see if there was any such change, the measures were freed from parallax, and means of four or five taken. These were plotted on a large scale. A thread was then tightly stretched over the measures and carefully adjusted to give the best representation. This straight line does not represent the observations with entire satisfaction. The best average, however, was obtained, and the deviations read off. These differences are given in connection with the mean measures. The ends of the thread would represent the positions $1900^{\circ} 943$, distance $36^{\prime \prime} \cdot 49$, and 1908.302, distance $43^{\prime \prime} \cdot 53$.

As these measures may be of interest to others, they are given below. The first column after the dates is the measured distance corrected for refraction, the next column gives the correction for parallax, while the last is the distance affected only by motion. The means of these and their deviation from the straight line are also given.

Distances (A C) corrected for parallax.

This investigation led me to notice that the direction of motion of A was regularly diminishing with the increase of time when derived from a comparison with the measures of 1890.8 . The motion was also slightly increasing. To find out the cause of this change I plotted the observations for each year (fig. 2), correcting the distances for parallax, and selecting the positions so that there would be but little parallactic change in the angles. No correction for precession has been applied to the position-angles. The extreme change due to this last cause would be $0^{\circ} \circ \circ$. The result shows that between the epochs 1890.8 to 1901.8 and igor. 8 to $1907^{\circ} 7$ there has been a total change of some $8^{\circ}$ or $9^{\circ}$ in the direction of motion. If we take the interval 1901.8-1907.7 the direction of motion is $239^{\circ}$, while the previous values were about $247^{\circ}$. A simple inspection of the diagram will show the change. It is evident, therefore, that the motion of $A$ is not rectilinear. This change is undoubtedly due to the orbital motion of A about the centre of gravity of the system. It is therefore not possible to give a value of its proper motion that will be constant for any considerable interval of time.

The following measures were used in constructing the diagram. The distances A C are corrected for parallax.

## The Micrometer Measures.

I have collected here for this paper all my published and unpublished measures of these stars, so that my work on the subject up to the present may be presented as completely as possible. All the distances have been corrected for refraction.

The diagram (fig. r) will show the relative positions of these various stars.

The measures follow.

| 1903.552 July 2I | $129^{\circ} 71$ | $46^{\prime \prime} 19$ |  |
| :--- | :--- | :--- | :--- |
| 1907.634 Aug. 20 | 129.4 I | 45.84 |  |
| $\frac{782 \text { Oct. 13 }}{1907.708}$ | $\frac{129.88}{129.65}$ | $\frac{45.98}{45.91}$ | $\frac{13.7}{13.7}$ |

It will be seen from the measures that the distance AB is begiuning to lessen, having attained a maximum about 1903 or 1904. The position-angle AC seems to have reached its greatest value about 1907 and is now slowly diminishing. Both changes are due to the orbital motion of $A$ in the system AB.

The following estimates of the magnitude of C were made at the time of the observations which have been included in Table I.

$$
\begin{array}{rrr}
\text { I900 } & \text { Dec. } & 8 \\
\text { I901 } & \text { Sept. } & 24 \\
9^{\circ} 5 \\
\text { 19.5 } & 9^{\circ} 5 \\
\text { Oct. } 2 \text { I } & 9^{\circ} 7 \\
\text { 1902 } & \text { Sept. } 29 & 9^{\circ} 9
\end{array}
$$

At the observation of 1900 Dec. 9 the following note occurs:"Both A and C are slightly yellowish."

Two small Double Stars near Krueger 60.
During these measures two small double stars were found and measured. Though they are not in any way connected with Krueger 60 , their proximity to this star, and the general resemblance of one of them to AB , would seem to warrant their insertion here.

The Following Component of No. 2 and a Faint Star North.

Additional measures of some of the stars have been inserted since this paper was submitted to the R.A.S.

Yerkes Observatory : 1908 May 18.

## Postscript.

I am very glad to be able to add to this paper the value of the parallax of Krueger 60 determined by Dr. Henry Norris Russell from photographs with the Cambridge (England) refractor. Dr. Russell has kindly supplied me with his value since my paper was put in type.

His result is :-

$$
\pi=+0^{\prime \prime} \cdot 25^{8} \pm 0^{\prime \prime} \cdot \mathrm{OI}_{3}
$$

from measures of $\Delta a$. Nine comparison stars were used, and the probable error for a single plate was $\pm 0^{\prime \prime} \cdot 026$.

The following, therefore, are all of the values of the parallax of this star known to me:

$$
\begin{aligned}
\text { Schlesinger } & =+0^{\prime \prime} \cdot 248 \pm 0^{\prime \prime} \cdot 009 \\
\text { Barnard } & =+0 \cdot 249 \pm 0 \cdot 010 \\
\text { Russell } & =+0 \cdot 258 \pm 0 \cdot 013
\end{aligned}
$$

Photograph containing three exposures of the double star Krueger 60 A B and the comparison star $C$. Taken with the 40 -inch refractor of the Yerkes Observatory, 1908 July 10 (enlarged). Exposures 10 minutes each. E. E Barnard.

[^0]:    * We have found that this last ternu is incorrectly given in Bessel's original paper, A.N. 366 , pp. 83-84, as $-\sin \delta \cos \mathrm{P} \sin \omega$.

    The same error occurs in the second of the formulæ for determining the parallax from the position-angle on the same page of $A . N ., 366$, the last term of which should also be $-\cos \delta \cos \mathrm{P} \cos \omega$.
