

## Accurate Positions of Selected 4C Sources

E. T. OLSEN

*Owens Valley Radio Observatory, California Institute of Technology*

(Received 9 May 1967)

Positions and flux densities at 1417 MHz of 490 radio sources have been measured using the two 90-ft steerable paraboloids at the Owens Valley Radio Observatory as an east-west and a north-south interferometer. After confusion has been taken into account, most of the positions are accurate to within  $\pm 20''$  in each coordinate and most flux densities to within  $\pm 0.1$  f.u. (One flux unit = 1 f.u. =  $10^{-26}$  W m $^{-2}$  Hz $^{-1}$ .)

### I. INTRODUCTION

A part of a continuing program of identification of radio sources with optical objects, positions and flux densities have been measured for 490 sources chosen from the  $20^\circ$  to  $40^\circ$  zone of the 4C catalogue (Pilkington and Scott 1965). The criteria used in selection were that the source must be more than  $10^\circ$  from the galactic plane and have a flux at 178 MHz of at least 2.5 f.u. The declination measurements were made with north-south baselines of  $1160\lambda$  (800 ft) and  $290\lambda$  (200 ft), and the right ascensions were determined using an east-west baseline of  $1160\lambda$  (800 ft). A single spacing in the E-W configuration was felt to be sufficient for the majority of the sources because the maximum quoted error for the right ascensions in the 4C catalogue is  $2^\circ 0$ , which is sufficiently accurate to preclude the possibility of lobe ambiguities. An east-west baseline of  $490\lambda$  (400 ft) was used to pick up approximately 50 sources in the region from  $21^\circ$  to  $1^\circ$  that were missed in the main series of observations; for these additional observations the frequency was determined by a concurrent program and was approximately 1200 MHz. The entire observation program was spread over a period of 16 months, and the schedule is presented in Table I.

All sources were observed for a minimum of 4 min, giving an rms noise of approximately 0.09 f.u. The mean positional error introduced by receiver noise is less than  $5''$ ; in the 800 ft observations this is comparable to the errors introduced by confusion and instrumental phase jitter, as discussed below. Almost all observations were made within 20 min of meridian transit.

TABLE I. Observation program.

Series	Observers <sup>a</sup>	Date	Baseline	Obs./Source
60 Brightest	2	Nov/65	$1160\lambda$ NS $1160\lambda$ EW	2 3
430 Remaining	1, 2	Feb-Mar/66	$1160\lambda$ NS $1160\lambda$ EW	1 2
430 Remaining	3	June/66	$290\lambda$ NS	3
60 Brightest pickup	1 3	Oct/66 Mar/67	$290\lambda$ NS $490\lambda$	2 2

### II. REDUCTION

The instrumentation used with the Owens Valley interferometer has been described by Read (1963), and the technique of reduction of the data has been sketched out by Fomalont, Wyndham, and Bartlett (1967). The positions of the radio sources were not measured on an absolute basis, but were determined relative to the known positions of certain "calibrator sources" drawn from the list given by Fomalont (1967). Most of these calibrators have been identified with quasi-stellar objects, and they are unresolved at the interferometer spacings used in the present observations. The flux densities are similarly determined relative to these calibrators, one of which was observed on the average every 2 h. The baseline parameters (the hour angle and declination of the point at which the extended baseline intersects the celestial sphere, and the length of the baseline measured in wavelengths of the observing frequency) were also determined, using a number of strong calibrators ranging in delination from  $-15^\circ$  to  $80^\circ$ , as described by Fomalont, Wyndham, and Bartlett (1967).

### III. ERRORS

There are four major sources of error in position and flux: changes in instrumental gain and phase, confusion by a nearby strong source, confusion by one or more unknown weak sources in the beam, and resolution of extended sources. The instrumental gain and phase are determined in the reduction program, and the jitter amounts to  $\pm 10$  millilobes in phase and  $\pm 10\%$  in gain for a single observation. The half-power beamwidth is  $34'$  at  $\lambda = 21$  cm, and a survey of the 3C catalogue (Edge, Shakeshaft, McAdam, Baldwin, and Archer 1959), the Parkes catalogue (Day, Shimmins, Ekers, and Cole 1965), and the NRAO catalogue (Pauliny-Toth, Wade, and Heeschen 1966) does not disclose a known source within  $20'$  of any of the selected 4C sources. Fomalont has investigated the confusion due to one or more unknown weak sources in the beam, and he has found the rms confusion at  $\lambda = 21$  cm to be 0.12 f.u. (Fomalont, Wyndham, and Bartlett 1967). The error due to possible resolution of some sources

can only be determined through a more detailed observation program. However, since only approximately 15% of the sources observed here exhibit a visibility at either 800-ft spacing which is less than one-half of that at the 200-ft spacing, the phase error due to resolution is assumed to be of minor importance. The final estimated error in position quoted in Table II is a worst-case combination of the instrumental error and confusion.

#### IV. SPECTRA OF THE 4C SOURCES

The spectral index  $\alpha$  for each source has been calculated using the 178 MHz flux densities quoted in the 4C catalogue and the 1417 MHz flux densities found at the Owens Valley Observatory from

$$S(\nu_2) = S(\nu_1)(\nu_2/\nu_1)^\alpha,$$

where  $\nu_1=178$  MHz,  $\nu_2=1417$  MHz, and  $S(\nu)$  is the flux density observed at frequency  $\nu$ . Figure 1 is a histogram of the spectral indices of 300 sources which were observed at all three spacings at 1417 MHz and whose declinations as determined by the two *NS* spacings did not differ by more than 30", indicating the absence of large-scale structure. The mean spectral index is  $\bar{\alpha}=-0.79 \pm 0.02$ , and the standard deviation is  $\sigma=0.19$ . The posing of more stringent conditions (for example, requiring that the three flux densities observed at the different antenna spacings agree to within 0.15 f.u.) does not alter these results. No dependence of  $\bar{\alpha}$  on flux density at 178 MHz is apparent. These results are in close agreement with the findings of Long, Smith, Stewart, and Williams (1966) and of Williams and Collins (1967).

#### V. DESCRIPTION OF TABLE II

The final results of the observations appear in Table II, which is arranged as follows:

Column 1. The name of the source as listed in the 4C catalogue. The sources are arranged in order of increasing right ascension.

Column 2. The right ascension in hours, minutes, and seconds of time (epoch 1950.0), followed by the estimated error in seconds of time and the spacing which was used to determine the position.  $A=800$  ft *EW*,  $C=400$  ft *EW*,  $D$  is the position originally quoted in the 4C catalogue.

Column 3. The declination in degrees, minutes, and second of arc (epoch 1950.0), followed by the estimated error in seconds of arc and the spacing which was used to determine the position.  $A=800$  ft *NS*,  $B=200$  ft *NS*,  $D$  is the position originally quoted in the 4C catalogue.

Column 4. The flux density at 1417 MHz. Usually this is the value found at the 200-ft *NS* spacing. In

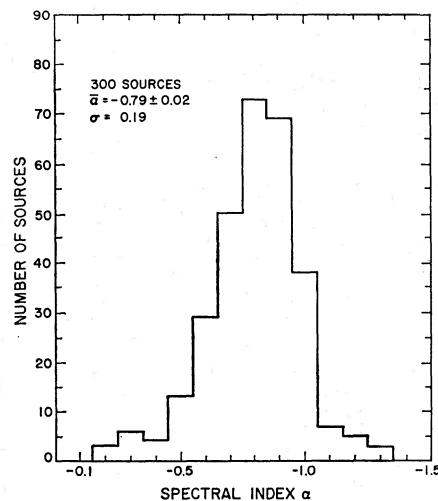

FIG. 1. Histogram of spectral indices for 300 selected sources.

some cases, however, the flux density observed at one of the longer spacings is significantly greater and is quoted here. The error in this value is approximately 0.1 f.u.

Column 5. The spectral index  $\alpha$  determined from the 178 MHz flux density quoted by Cambridge and the 1417 MHz flux density appearing here.

Column 6. Reference to the following notes: (1) Unresolved at 800-ft spacings. The 1417 MHz flux densities determined at the three spacings must agree to within 0.2 f.u. (2) Partially resolved at the 800-ft *EW* spacing. The flux density observed at this spacing is lower than that observed at the 200-ft *NS* spacing by at least 0.3 f.u. (3) Partially resolved at the 800-ft *NS* spacing. The flux density observed at this spacing is less than that observed at the 200-ft *NS* spacing by at least 0.3 f.u. (4) Partially resolved at both of the 800-ft spacings. (5) The positions determined from the two *NS* spacings disagree by more than 60" and/or the flux density at one or both 800-ft spacings is at least 0.3 f.u. greater than that of the 200-ft *NS* spacing. These discrepancies are probably due to large-scale structure or confusion. (6) Probably undetected; the flux density at all spacings is less than 0.2 f.u.

Column 7. The name of the source as it appears in the 3C, Parkes, or NRAO catalogues.

At this time the optical fields of these positions are being studied and the identifications will appear in a forthcoming paper.

#### ACKNOWLEDGMENTS

I wish to particularly thank, G. J. Stanley, J. D. Wyndham, A. T. Moffet, E. B. Fomalont, D. H. Rogstad, and J. F. Bartlett for giving freely of their time to make this paper possible. I also thank K. Weiler, C. Spencer,

E. Aubin, and the half-dozen students in space physics who aided in the observations.

The program of research in radio astronomy at the California Institute of Technology is supported by the U. S. Office of Naval Research under contract N00014-67-A-0094-0008.
